## data variables

### Comparing depression trends between April 2020 and April 2018

```
##  
## Paired t-test  
##  
## data: d2020 and d2018  
## t = 0.75536, df = 29, p-value = 0.4561  
## alternative hypothesis: true difference in means is not equal to 0  
## 95 percent confidence interval:  
## -3.813702 8.280369  
## sample estimates:  
## mean of the differences  
## 2.233333
```

The null hypothesis is that there is no difference in the mean amount of depression searches in the US between the times of April 2020 and April 2018. The alternate hypothesis is that there is a difference between the two means. Assuming that the null hypothesis is true, the model follows a t-distribution. The t-statistic is 0.755 and the  $df = 29$ . This corresponds to a p-value of 0.4561. We cannot reject the null at the  $\alpha = 0.05$  level. We do not have enough evidence to claim that there is a difference in the mean amount of depression searches in the US between the times of April 2020 and April 2018.

## Restriction vs. depression rate

### Depression rate in each state map

```
library(usmap)  
library(ggplot2)  
  
plot_usmap(data = dstate, values = "depression", color = "red") +  
  scale_fill_continuous(name = "depression searches", label = scales::comma) +  
  theme(legend.position = "right")
```

```
## Warning: Use of `map_df$x` is discouraged. Use `x` instead.
```

```
## Warning: Use of `map_df$y` is discouraged. Use `y` instead.
```

```
## Warning: Use of `map_df$group` is discouraged. Use `group` instead.
```
